MOLECULAR SYSTEMATICS OF THE CHINESE *YINSHANIA* (BRASSICACEAE): EVIDENCE FROM PLASTID AND NUCLEAR ITS DNA SEQUENCE DATA<sup>1</sup>

Marcus Koch<sup>2</sup> and Ihsan A. Al-Shehbaz<sup>3</sup>

#### ABSTRACT

Species of the Chinese endemic genera Yinshania, Hilliella, and Cochleariella were originally placed in or closely associated with Cochlearia. A previous preliminary molecular study mainly on European Cochlearia and detailed morphological studies by us showed that this complex was not affined to Cochlearia s. str. Depending on the authority consulted, the number of taxa recognized in this complex ranged from 11 to 25 species in one to four genera. The present phylogenetic study is based on the analysis of the ITS (internal transcribed spacer regions of the nuclear ribosomal DNA) and the chloroplast trnL-intron sequences from 18 taxa. Resulting phylogenies were compared, and the results demonstrate that there are two different lineages. One lineage combines exclusively the highly polyploid taxa from Hilliella and Cochleariella. The second lineage includes the diploid taxa from Yinshania. However, incongruencies when nrDNA- and cpDNA-derived phylogenies were compared suggest hybridization between these two lineages. We followed a concept to combine all taxa of this complex into the genus Yinshania. Our results from phylogenetic analysis of nr and cpDNA support the association of Yinshania with Cardamine and Rorippa, rather than with Cochlearia, as was suggested by nearly all previous authors.

Key words: Brassicaceae, Cochleariella, Hilliella, molecular systematics, reticulate evolution, Yinshania.

Many authors follow Schulz (1936) and Schultze-Motel (1986) in dividing Cochlearia into the sections Pseudosempervivum Boiss., Glaucocochleria O. E. Schulz, Cochlearia (= Eucochlearia Prantl), and Hilliella O. E. Schulz. As shown by Koch et al. (1999a), however, this sectional classification is highly artificial. Section Cochlearia is widely distributed in Europe and the circumpolar region, whereas section Glaucocochlearia, which was raised to the generic rank by Pobedimova (1968), is restricted to southwestern Europe. The latter section consists of C. glastifolia L. and C. megalosperma (Maire) Vogt, as well as C. aragonensis Coste & Soulié, which was only recently included (Koch et al., 1996), although considered to be distantly related to the other two species (Koch et al., 1999a). Section Cochlearia consists of a species complex that demonstrates highly polymorphic chromosome numbers, and diverse ecological adaptation and geographic distributions. Morphological differences between phylogenetically sister taxa are often weak and poorly defined (Koch et al., 1996). Both sections Cochlearia and Glaucocochlearia are closely related to the genus Ionopsidium

Rchb. (Koch et al., 1999a). Section Pseudosempervivum, which is centered in the Middle East and clearly unrelated to Cochlearia, is most closely related to Masmenia F. K. Mey. and Noccaea Moench (Koch et al., 1999a), both of which were segregated by Meyer (1973, 1979, 1991) from Thlaspi L. s.l. The family of Brassicaceae is divided into several tribes and subtribes. Most of them are highly artificial, such as tribe Arabideae (Koch et al., 1999b) or Lepidieae (Zunk et al., 1996). Following classical tribal concepts, Cochlearia sect. Pseudosempervivum, sect. Cochlearia, and sect. Glaucocochlearia are members of tribe Lepidieae. Species originally assigned by Schulz (1923) to section Hilliella (Yinshania, Hilliella, and Cochleariella) were excluded from Cochlearia by Pobedimova (1970), who did not assign them to any genus. However, these species have recently been placed in three Chinese endemic genera, Yinshania Y. C. Ma & Y. Z. Zhao, Cochleariella Y. H. Zhang & Vogt, and Hilliella (O. E. Schulz) Y. H. Zhang, each of which was assigned to a different subtribe. The genus Yinshania (Ma & Zhao, 1979) was placed in subtribe

<sup>1</sup>We are grateful to Zhang Yu-hua for providing some of the samples. The curators of A, B, BM, E, GH, HAST, IBSC, K, KUN, LE, MO, NAS, NY, P, PE, TAI, TI, TNS, US, W, and WU are thanked for the loan of specimens. <sup>2</sup>Institute of Botany, University for Agricultural Science, Gregor-Mendel-Str. 33, A-1180 Vienna, Austria. <sup>3</sup>Missouri Botanical Garden, P.O. #### Koch & Al-Shehbaz Chinese Yinshania

Descurainiinae, tribe Sisymbrieae. The genus Cochleariopsis (Zhang, 1985), renamed as Cochleariella (Zhang & Cai, 1989), was placed in subtribe Cochleariinae, tribe Lepidieae, along with Hilliella s. str. (Zhang, 1986). Although a few studies on taxonomy, evolution, and origin of these genera (Zhang, 1987; Zhang & Xu, 1990; Zhang, 1993) have been made, nothing was said about their systematic position in relation to the remaining Asian and European taxa of Cochlearia. Zhang's (1987) division of Yinshania (excluding Hilliella) into two sections and two series and Zhao's (1992) classification of Yinshania (including Hilliella) into two sections and six series, were shown by Al-Shehbaz et al. (1998) to be highly artificial. In fact, one of the species assigned by Zhang (1987) to Hilliella and by Zhao (1992) to Yinshania was placed by Al-Shehbaz and Yang (1998) in the synonymy of Cardamine fragariifolia O. E. Schulz. On the basis of a comprehensive morphological survey of Yinshania, Hilliella, and Cochleariella, Al-Shehbaz et al. (1998) reduced the latter two to synonymy of Yinshania, and concluded that there is no need for infrageneric subdivisions that do not reflect the phylogenetic relationships of this small

tributions to a better understanding of the classification, generic delimitation, and phylogenetic relationships in the Brassicaceae. A preliminary study (Koch et al., 1999a) utilizing ITS nrDNA and cp trnL intron sequence data of four species of the Yinshania complex (including Hilliella and Cochleariella) clearly showed that the complex is unrelated to Cochlearia. In this analysis it has been shown that ITS and trnL intron sequence data provide sufficient sequence variation to distinguish significantly between Yinshania and Cochleariella/ Hilliella accessions with both data sets. In order to gain a better insight of the phylogenetic relationships within this Chinese complex, we examined sequence variation of the internal spacer regions (ITS1 and ITS2) of nrDNA (Baldwin et al., 1995; Campbell et al., 1995) and of the cp trnL intron (Böhle et al., 1994; Gielly & Taberlet, 1994; van Ham et al., 1994; Koch et al., 1999a), and compared the derived molecular phylogenies with traditional concepts based on morphological data. This approach provided us with the opportunity to characterize species lineages and to analyze incongruencies between different data sets in order to test hypotheses of gene flow over lineages and chlo-

genus of 13 species.

They also demonstrated that morphological characters previously used in the delimitation of species (e.g., density of papillae on the fruit valves, fruit shape, and seed number per fruit) are highly variable among and within different populations of the same species. Furthermore, differences in the compression of fruit (terete vs. latiseptate or angustiseptate) that were emphasized heavily by earlier authors (e.g., Schulz, 1936) in the delineation of genera were not found to be taxonomically useful in the Yinshania complex. As shown by Koch et al. (1999a), the placement of heavy emphasis on fruit compression has led to the artificial integration of several taxa into Cochlearia sect. Pseudosempervivum instead of Thlaspi s.l. In fact, terete and variously flattened fruits occur in numerous genera of the Brassicaceae, and in many cases this aspect of fruit morphology is taxonomically insignificant. Morphological convergence and parallelism are widespread in the Brassicaceae (Dvorák, 1971; Meyer, 1973; Avetesian, 1983; Endress, 1992), and the dependence on such characters to construct phylogenies often leads to erroneous conclusions (Sytsma, 1990; Meyer, 1991). Recent molecular analyses (e.g., Warwick et al., 1992; Price et al., 1994; Mummenhoff & Koch, 1994; Zunk et al., 1996; Mummenhoff et al., 1997; Koch et al., 1998a, b; Koch et al., 1999a, b) have made significant conroplast capture.

#### MATERIALS AND METHODS

#### PLANT MATERIAL

Leaf material for DNA extraction was obtained from herbarium specimens (Table 1), most of which were provided and determined by Zhang Yu-hua (Institute of Materia Medica, Zhejiang Academy of Medicine, Hangzhou, People's Republic of China). We did not examine vouchers to verify Zhang's determinations. The samples represent a broad spectrum of species of *Yinshania*, *Hilliella*, and *Cochleariella*. *Cardamine flexuosa* With. and *Rorippa palustris* (L.) Besser served as the outgroups. The DNA sequences for the outgroups were obtained from Franzke et al. (1998).

DNA EXTRACTION, PCR-AMPLIFICATION, AND SEQUENCING

The total DNA for the outgroups was isolated from leaf tissues following the CTAB (cethyltriammoniumbromide) method of Doyle and Doyle (1987), as modified by Mummenhoff and Koch (1994). DNA extraction from herbarium material was performed in a mini preparation in Eppendorf reaction tubes from 50-µg dried tissue. Tissue was ground with sand and prewarmed 2X CTAB-buffer. provided by Zhang, 22 through 26

-------------------------------

Organic extraction and DNA isolation from herbarium specimens followed Koch et al. (1996).

Double-stranded DNA of the complete ITS region, including the 5.8S rDNA gene, was amplified by 30 cycles of symmetric PCR using ITS primers initially designed by White et al. (1990) and modified by Mummenhoff et al. (1997). The 18F primer (5'-GGAAGGAGAAGTCGTAACAAGG-3') is located at the 3'-end of the 18S rDNA gene, and primer 25R (5'-TCCTCCGCTTATTGATATGC-3') is located at the 5'-end of the 25S rDNA. It has been reported that PCR selection of rDNA paralogues has occurred (Buckler et al., 1997). However, PCR selection might have only been important in high G+C content sequences (Buckler et al., 1997). Sequences from Yinshania and Hilliella (Koch et al., 1999a) are comparable in G+C content to sequences from Gossypium, in which PCR selection was probably weak (Wendel et al., 1995a). The resulting amplification product included ITS1, 5.8S rDNA, and ITS2. Only those PCR products were cloned into the pGEM-T-Easy cloning vector (PROMEGA) that showed a single band on ethidium bromide stained agarose gels. Two cloned ITS regions from two independent PCR reactions were sequenced (forward and reverse) with both amplification primers and two universal primers located in the flanking sites of the pGEM-T-Easy vector (t7forward: 5'-gtaacgatttaggtgacactatcg-3, m13-reverse: 5'-agcggataacaatttcacacagga-3). This means that every single clone was sequenced four times to avoid sequence errors. The trnL (UAA) intron was amplified and sequenced by using the universal primer B49318 (5'-CGAAATCGGTAGACGCT-ACG-3') located at the 3'-end of the trnL(UAA)5'exon and A49855 (5'-GGGGATAGAGGGACTTG-AAC-3') located at the 5'-end of the trnL(UAA)3'exon (Taberlet et al., 1991). The PCR profile used to amplify the trnL intron followed the following profile: hot start with 5 min. at 94°C, and 35 cycles of amplification (1 min. 94°C, 45 min. 50°C, 45 min. 72°C), final elongation step for 10 min. 72°C, and storage at 4°C. DNAs were cycle-sequenced using the Taq DyeDeoxy Terminator Cycle Sequencing Kit (ABI Applied Biosystems, Inc.). Products of the cycle sequencing reactions were run on an ABI 377XL automated sequencer (ABI Applied Biosystems, Inc.). Material from accession numbers 22-26 (Table 1) was only used for sequencing the trnL intron sequence, because amplification of the ITS regions failed totally.

to those of Sinapis alba L. (Rathgeber & Capesius, 1989) and other Brassicaceae (Mummenhoff et al., 1997; Koch et al., 1999a). DNA sequences were aligned by hand. Parsimony analyses were performed with unordered Fitch parsimony and weighted parsimony with a transition: transversion weighting of 1.0:1.08 using PAUP version 3.1 (Swofford, 1993). The BRANCH-AND-BOUND algorithm was used to find maximally parsimonious trees. Bootstrap analysis (Felsenstein, 1985) was performed using 1000 replicates and the HEURIS-TIC search algorithm with the MULPARS option. We combined the GAPMODE=MISSING option with the coding of the gaps as additional presence/ absence characters (Downie & Katz-Downie, 1996). This option decreases the number of equally parsimonious trees because of the redundancy resulting from having two sets of scored characters for the same indel events (Wojciechowski et al., 1993). Evolutionary data are most often presented as a phylogenetic tree, the underlying assumption being that evolution is a branching process. However, empirical data is rarely ideal and often supports several trees instead of one unique tree. Hence, it makes sense to consider tree reconstruction methods that produce a tree if the given data heavily favor one tree over all others. Otherwise, methods that produce a more general graph that indicates different possible phylogenies are useful (Huson, 1998). One such method is the Split Decomposition introduced by Bandelt and Dress (1992) and its variations. In order to visualize conflicting phylogenetic signals, we analyzed all ingroup ITS sequences (see Fig. 6), using the software program SplitsTree version 1.0.3. (Huson & Wetzel, 1995 shareware ftp://ftp.uni-bielefeld.de/pub/math/splits/). trnL intron data. DNA sequences were aligned by hand. Parsimony analysis was performed with PAUP (version 3.1; for options, see ITS data). Gaps were treated as additional unweighted binary characters. These gaps were coded using strict criteria: gaps must occur at the same position and have the same aligned length to be treated as homologous, and no splitting of one gap in two or more characters was performed (Koch et al., 1999a). Bootstrap analysis was performed as described above.

#### DATA ANALYSIS

ITS data. Boundaries of the ITS regions and coding sequences were determined by comparison

#### TRIBAL RELATIONSHIPS

To estimate the tribal affinity of Yinshania, we derived an ITS phylogeny with sequences from Capsella rubella Reut. (Koch et al., 1999b), Arabidopsis thaliana (L.) Heynh. (GenBank U43224), Yinshania acutangula (O. E. Schulz) Y. H. Zhang,

#### Koch & Al-Shehbaz Chinese Yinshania

251

Barbarea vulgaris R. Br. (EMBO X98632), Cardamine flexuosa With. (Franzke et al., 1998), Thlaspi arvense L. (Koch et al., 1999a), Cochlearia aestuaria (Lloyd) Heywood (Koch et al., 1999a), Brassica oleracea L. (GenBank AF039994/AF040038), and Sinapis alba (EMBO X66325). DNA sequences were aligned by hand, and the alignment is shown in Figure 4. Alignment positions 109-160 were removed from subsequent analysis. Parsimony analyses were performed with unordered Fitch parsimony using PAUP version 3.1 (Swofford, 1993). The BRANCH-AND-BOUND algorithm was used to find maximally parsimonious trees with the GAP-**MODE = NEWSTATE** option. Bootstrap analysis (Felsenstein, 1985) was performed using 1000 replicates and the HEURISTIC search algorithm employed with the MULPARS option. A decay analysis (Bremer, 1988) was performed in addition to the bootstrap approach, in order to assess the confidence that could be placed in the monophyly of clades. Decay indices (DI) were estimated according to Baum et al. (1994).

cluding the additional 0/1 matrix for the gap position, resulted in 24 most parsimonious trees (MPTs) with a length of 538 and a consistency index (CI) of 71.4% (66.9% if autapomorphies are excluded). Of the 264 variable nucleotide positions, 166 informative positions were in the ITS1 region (including 48 autapomorphies) and 98 in the ITS2 region (including 25 autapomorphies). Four out of 36 gap positions within the total sequence alignment are unique to a particular sequence (Rorippa palustris 2 gaps, acc. no. 3, and acc. no. 14). A calculation of the transition/transversion ratio for the MPTs revealed a ratio of 1.00:1.08. Therefore, we used a weighted parsimony approach with a character state weighting of 1.00:1.08 (transition: transversion), which resulted in one MPT that is also represented among the 24 MPTs from the Fitch parsimony with a consistency index of 67.7% (CI 57.9% if autapomorphies were excluded). We present the MPT from the weighted parsimony approach to demonstrate relative branch length (Fig. 2). Bootstrap values are provided from 1000 replicates using the weighted parsimony approach. For most taxa we identified only one ITS sequence type within a single specimen. For Hilliella lichuanensis Y. H. Zhang (acc. no. 13), Cochleariella zhejiangensis (Y. H. Zhang) Y. H. Zhang & R. Vogt (acc. no. 21), Yinshania acutangula (acc. no. 5), Y. henryi (Oliv.) Y. H. Zhang (acc. no. 7), and Y. furcatopilosa (K. C. Kuan) Y. H. Zhang (acc. no. 8), we found two very similar ITS sequences among the two clones sequenced. In the case of accession numbers 13, 5, 7, and 8, ITS1 and ITS2 regions differed by only a single site mutation. In the case of C. zhejiangensis (acc. no. 21), the two ITS types from the same individual differed by 15 mutations, which might indicate that two different ITS loci were cloned and sequenced. Both sequences clustered within the same clade. In Hilliella fumarioides (Dunn) Y. H. Zhang & H. W. Li (acc. no. 17), we detected two ITS sequences from a single individual that clustered in different clades (Figs. 2, 6). Both sequences differed by 76 mutations. The ITS data clearly support a separation of two clades consisting of Yinshania sensu Zhang (1987) and Hilliella/Cochleariella. Different accessions from one taxon (sensu Al-Shehbaz et al., 1998, refer to fig. 2) grouped at different positions in the case of C. zhejiangensis (acc. no. 20, not related to acc. nos. 18, 19, 21).

RESULTS

ITS DATA

The total length of the alignment with accession numbers 1-21 and outgroups Cardamine flexuosa and Rorippa palustris is 464 bp, with 283 and 181 nucleotides in ITS1 and ITS2 spacer regions, respectively. The alignment required 36 (7.8%) gap positions, including the outgroups, and is shown in Figure 1. Sequence data were submitted to Gen-Bank with accession numbers AF100793-AF100852 (Table 1). One third of these gaps is located between positions 117 and 133 in the ITS1. This region was completely excluded from subsequent analysis. Additionally, we excluded nucleotide position 465-467 and 473-484 from subsequent data analysis because of an ambiguous alignment (Fig. 1). Gaps from nucleotide positions 11-14 and 293-294 were treated as one single gap, respectively. The number of introduced gaps is comparable to a phylogenetic analysis of Thlaspi s.l. with 4.8% of the sites (Mummenhoff et al., 1997). In Krigia and outgroups, Kim and Jansen (1994) had to introduce gaps in 3.9% of the sites. Total lengths of ITS1 and ITS2 are nearly identical among the taxa surveyed, and vary between 447 bp (Hilliella alatipes (Hand.-Mazz.) Y. H. Zhang & H. W. Li var. micrantha Y. H. Zhang [= Yinshania rivulorum (Dunn) Al-Shehbaz et al.], accession no. 10) and 457 bp (Cardamine flexuosa and Rorippa palustris).

Phylogenetic analysis using Fitch parsimony, in-

Using the taxonomic concept of Al-Shehbaz et al. (1998) and merging *Hilliella changhuaensis* Y. H. Zhang, *H. guangdongensis* Y. H. Zhang, and *H. lichuanensis* (acc. nos. 11, 12, 13, respectively) into *H. lichuanensis*, only accession numbers 11 and 13

## Koch & Al-Shehbaz Chinese Yinshania

grouped together by ITS data. Accession number 12 (H. guangdongensis) is unrelated to these accessions based on ITS data. Similarly, H. warburgii (O. E. Schulz) Y. H. Zhang & H. W. Li (acc. nos. 18, 19), Cochleariella zhejiangensis (acc. nos. 20, 21), and H. fumarioides (acc. no. 17) merge into Y. fumarioides (Dunn) Y. Z. Zhao, as proposed by Al-Shehbaz et al. (1998). ITS sequences from Y. fumarioides sensu Al-Shehbaz et al. (1998) are found in three different positions among the Hilliella/ Cochleariella clade (Fig. 2).

no. 12), C. zhejiangensis (acc. no. 20), and H. alatipes var. micrantha (acc. no. 10). Remaining Hilliella/Cochleariella taxa appeared in this analysis for trnL data excluding gap information as a sister group to these two clades. Nonetheless, integration of Yinshania qianningensis Y. H. Zhang into the Hilliella/Cochleariella clade is significant for trnL data, in contrast to its segregation by ITS. Estimation of decay indices (DI) using the trnL intron matrix without gap information revealed a high value, DI = 3+, for the branch setting of the Yinshania clade. Different accessions of C. zhejiangensis (acc. nos. 20, 21) did not group closely together; this has also been documented for the ITS data gensis, and H. lichuanensis do not group together in the cpDNA-based tree as proposed by the morand H. fumarioides. Based on the trnL sequence data, they are not combined in one single clade that could be named as H. fumarioides as proposed in

259

trnL DATA

The alignment of 514 bp is interspersed with (Figs. 2, 6). Hilliella changhuaensis, H. guangdonseven gaps as shown in Figure 3. Sequence data were submitted to GenBank with accession numbers AF100853 through AF100881 (Table 1). The phology-based concept combining them in H. lilengths of *trnL* intron sequences range from 311 bp chuanensis (Al-Shehbaz et al., 1998); the same disin Hilliella rivulorum to 514 bp in Cardamine flexcordance holds for H. warburgii, C. zhejiangensis, uosa. Of the 38 variable nucleotide positions in the alignment, 12 sites are autapomorphic. In addition, one of the seven gaps is autapomorphic. Phylogenetic analysis resulted in two MPTs with a length the revison of Al-Shehbaz et al. (1998). of 53 steps and a consistency index of 92.5% (90.0% if autapomorphies were excluded). One ITS VERSUS TRNL INTRON DATA most parsimonious tree is shown to demonstrate rel-Both phylogenetic trees (ITS vs. trnL data) from ative branch length. The strict consensus tree could Figure 2 show some congruencies (all following arbe generated easily by drawing branches that are guments are also true when comparing the strict indicated in Figure 2 by heavy bars with zero consensus trees from Fitch parsimony, which could length. Bootstrap values are given from 1000 repbe easily deduced by drawing branches indicated licates. by heavy bars with zero length): Discrimination of a Yinshania clade from a Cochleariella/Hilliella clade is not as obvious with trnL which has been merged in H. lichuanensis sensu intron data as compared to ITS sequence data (Fig. 2). In the trnL tree the branch setting of the Yin-Al-Shehbaz et al. (1998), is separated from remainshania clade as a sister group to the Hilliella/Coching H. lichuanensis sensu Al-Shehbaz et al. (1998), and it is more closely related to H. hunanensis, a leariella clade is not highly supported, and boottaxon that was recognized by Al-Shehbaz et al. strap value for this branching point is less than 50% (Fig. 2). Removing additional gap characters (1998).(2) Hilliella warburgii and Cochleariella zhejianfrom the matrix parsimony analysis resulted in one MPT with the Yinshania clade as a sister group to H. hunanensis (acc. no. 16), H. guandongensis (acc.

(1) Hilliella guangdongensis [sensu Zhang],

gensis are not integrated into H. fumarioides sensu Al-Shehbaz et al. (1998), but (3) most accessions

 $\leftarrow$ 

Figure 2. Comparison of the ITS-derived phylogeny with those from the trnL sequence data from Yinshania, Cochleariella, and Hilliella, as well as outgroups Cardamine and Rorippa from subtribe Arabideae (Brassicaceae). Accession enumeration in brackets follows Table 1. For the ITS and the trnL tree the nomenclature sensu Zhang (1985, 1986, 1987, 1993) has been used. In between both trees the taxonomic treatment of these taxa according to Al-Shehbaz et al. (1998) is shown. The most parsimonious tree (weighted parsimony approach) from ITS nuclear sequence data and one out of two MPTs from the trnL plastid sequence data is shown to demonstrate relative branch length. Weakly supported branches that collapsed in the strict consensus trees using Fitch parsimony are highlighted by a broad line. (The strict consensus trees could therefore be easily generated by drawing broad lines as zero branches.) Bootstrap values are provided from 1000 replicates and shown above branches if greater than 50%. Distance scale indicating branch lengths is given below. ITS designation (a) and (b) of accession nos. 5, 7, 8, 13, 17, and 21 indicate different **ITS** types from a single individual.

263

of H. warburgii and C. zhejiangensis formed one single cluster with no separation of H. warburgii versus C. zhejiangensis. This is in agreement with previous concepts combining both taxa, C. zhejiangensis and H. warburgii, in one single taxon. These congruent ITS and trnL intron findings demonstrate that both Y. lichuanensis and Y. fumarioides species complexes, treated as well-defined taxa according to the morphological revision of Al-Shehbaz et al. (1998), do not form monophyletic groups by molecular evidences. However, some incongruencies among the two molecular data sets could be detected: (1) Yinshania gianningensis grouped either inside the Hilliella/ Cochleariella clade (trnL intron data) or into Yinshania s. str. (ITS data); (2) H. rupicola (D. C. Zhang & J. Z. Shao) Y. H. Zhang also clustered into two different subgroups within Hilliella/Cochleariella.

and related taxa are closer to *Cardamine* and *Barbarea* from tribe Arabideae than to genera like *Thlaspi* or *Cochlearia* s. str. of the tribe Lepidieae.

#### Cytology

Little is known about the cytology of Yinshania. Zhang (1995, and pers. comm.) counted 2n = 12for Y. qianningensis Y. H. Zhang [= Y. acutangula sensu Al-Shehbaz et al., 1998], Y. henryi (Oliv.) Y. H. Zhang, and Y. furcatopilosa (K. C. Kuan) Y. H. Zhang, 2n = 42 for Hilliella yixianensis Y. H. Zhang, H. paradoxa (Hance) Y. H. Zhang & H. W. Li, and H. changhuaensis [= Y. lichuanensis sensuAl-Shehbaz et al., 1998], and 2n = 44 for H. shuangpaiensis Z. Y. Li [= Y. rupicola sensu Al-Shehbaz et al., 1998]. These data correspond to the ITS-derived phylogeny, in which the diploid Y. qianningensis, Y. henryi, and Y. furcatopilosa, together with Y. acutangula, are separated from the polyploid Hilliella. Within polyploid Hilliella, the Hilliella taxa with 2n = 42 are combined. Hilliella shuangpaiensis (represented in this study by acc. no. 4, Fig. 2) with 2n = 44 did not group closely to the known 2n = 42 taxa (represented in this study by acc. nos. 2, 11, and 15, Fig. 2). However, any conclusions based on cytology must be only preliminary. It remains possible that the Hilliella/ Cochleariella group could also be represented by polyploid taxa with 2n = 42 and 44. Base chromosome number for this hexaploid group is x = 7, instead of x = 6 as in the Yinshania group. A few taxa within the Hilliella/Cochleariella clade may be aneuploids (2n = 44) that derived from 2n = 42.

#### TRIBAL RELATIONSHIPS

The alignment of ITS1-5.8SrDNA-ITS2 is 644bp in length (Fig. 4). Within the ITS1 region (bp 1-301) there are 143 variable nucleotide positions (including 62 autapomorphies). The ITS2 region (position 456-644) contains 85 variable nucleotide positions (including 57 autapomorphies). The 5.8S rDNA gene, located between both spacer regions (bp 302-455), contains 11 variable nucleotide positions (including 6 autapomorphies). Because of an ambiguous alignment, nucleotide positions 107-153 and 460-484 were removed from the original data matrix (Fig. 4), resulting in a final data matrix of 412 bp. Fitch parsimony analysis resulted in one MPT with a length of 288 steps and a consistency index of 79.5% (66.5% if autapomorphies are excluded). The phylogenetic tree (Fig. 5) showed closer relationships of Yinshania to taxa from tribe Arabideae sensu Janchen (1942) (Arabidopsis (DC.) Heynh., Barbarea R. Br., and Cardamine L. were used to represent tribe Arabideae). However, Cochlearia (including species loosely affined to the Yinshania complex) and Capsella rubella were placed by Janchen in the tribe Lepidieae, where they had been put by Hayek (1911) and Schulz (1936). Our ITS data do not support this latter placement. A molecular analysis of Arabidopsis, Arabis L., and their relatives shows a close relationship of Capsella rubella to Arabidopsis thaliana (Koch et al., 1999b). Also demonstrated is the polyphyly of Arabis and Arabidopsis, indicating that tribal structures within Brassicaceae are highly artificial. The **ITS** phylogeny does suggest that Chinese Yinshania

#### DISTRIBUTION

Some interesting features emerge when topologies of the phylogenetic trees are compared to the geographic distribution of Yinshania s.l. Geographic distribution of ITS sequence types from taxa of the four main clades within Hilliella/Cochleariella do not follow their phylogenetic relationships (Fig. 7), and they are randomly mixed in Southeast China in the provinces of Guangdong, Jiangxi, Zhejang, Anhui, Hubei, and eastern Sichuan. However, they are separated geographically and phylogenetically from the Yinshania clade from Hunan, Xizang, and Sichuan. Taxa from the Yinshania clade extend the distribution to the southwest. A mixed distribution of DNA types also holds for the trnL data. No geographic structuring of plastome types could be observed among taxa from the Hilliella/Cochleariella clade (Fig. 8). Based on trnL intron data Y. gianningensis (acc. no. 1) from Sichuan integrates into the Hilliella/Cochleariella clade. Geographically,

Figure 4. Continued.

#### Koch & Al-Shehbaz Chinese Yinshania

Figure 5. Phylogenetic relationships of cruciferous taxa from different tribes. Genetic distances were calculated using the program TREECON (van de Peer & de Wachter, 1994) under the Kimura model (Kimura, 1980). Gaps were not taken into account, and the neighbor joining algorithm was used to calculate genetic distances. The robustness of the tree was tested by 1000 bootstrap replicates.

Figure 6. Split Decomposition of the ITS sequence data set analyzing the ingroup taxa. The DRAW-EQUAL-EDGES option was used to draw the network, and thus distances are not drawn to scale.

			(		
95°	100°	105°	110°	115°	120°

Figure 7. Distribution of ITS types among *Yinshania* and *Hilliella/Cochleariella* accessions under study in China. Taxon enumeration follows Table 1. The *Hilliella-Cochleariella* clade is separated into four ITS types indicated by circles and boxes (gray or white) well supported by high bootstrap values in Figure 2. Accessions marked by open circles and boxes are two well-separated subgroups, which are combined to a single group in Figure 8 (plastid *trnL* data). Phylogenetic relationships are shown schematically in the upper left box and follow Figure 2. For the *Yinshania* clade phylogenetic relationships are shown to demonstrate the position of *Yinshania qianningensis* [*Y. acutangula* sensu Al-Shehbaz] (acc. no. 1) (refer to Fig. 2).

this accession lies close to a similar plastome type (acc. no. 15) from the Hilliella/Cochleariella clade (Fig. 8). Upon comparison of the ITS and trnL intron-derived phylogenies, taxa that showed different positions in the phylogenetic analysis (e.g., H. rupicola, acc. no. 14; H. fumarioides, acc. no. 17: one additional ITS sequence copy) were located at the center of the Hilliella/Cochleariella distributional area. We interpret these results as a first biogeographical documentation of reticulation within polyploids. Hilliella fumarioides (acc. no. 17) possessed a trnL intron type similar to samples from surrounding areas. The two ITS types found in that particular individual were also present in adjacent regions and from different species. From Hilliella rupicola (acc. no. 14) we could isolate an ITS DNA type, which is also present in adjacent regions in accession numbers 10, 16, 17, and 20. trnL intron DNA type from accession number 14 also corre-

sponds to trnL intron DNA types from 2, 3, 11, 13, 17, and 20.

MORPHOLOGICAL VARIATION AND TAXONOMIC CONSIDERATIONS

As in numerous other cases in the Brassicaceae, morphological differentiation among and within socalled genera and taxa of the *Yinshania* s.l. complex does not provide ample characters to draw sharp and uncontroversial generic boundaries. Flower morphology in the entire complex is of no predictive diagnostic value, even for the separation of species (Al-Shehbaz et al., 1998). Only leaves and fruits offer characters useful for the separation of species, and all taxa appear to be not well defined. As shown by Al-Shehbaz et al. (1998), seed sculpture and number per locule, cotyledonary position, development of the fruit septum, type (if any)

Figure 8. Distribution of *trnL* intron types among *Yinshania* and *Hilliella/Cochleariella* accessions under study in China. Taxon enumeration follows Table 1. The *Hilliella-Cochleariella* clade is separated into three plastid *trnL* types indicated by circles and boxes (gray or white) well supported by high bootstrap values in Figure 2. Phylogenetic relationships are shown schematically in the upper left box and follow Figure 2. For the *Yinshania* clade phylogenetic relationships are shown to demonstrate the position of *Yinshania qianningensis* [*Y. acutangula* sensu Al-Shehbaz] (acc. no. 1) (refer to Fig. 2).

of fruit compression, fruit shape, development of papillae on the fruit valve, and trichome type, all are unreliable in dividing the complex into the genera Yinshania, Hilliella, and Cochleariella. In fact, no single character or set of characters can be relied upon to subdivide the complex into generic or infrageneric taxa. The recognition of a single genus is, therefore, taxonomically expedient, as there is no single character setting one clade apart from another. Even pustules on the testa surface of the valves, which were assumed to be a good character to separate Yinshania (pustules present) from Hilliella (Zhang & Xu, 1990), appear not to be congruent, failing to provide a good argument to split Yinshania into several genera (Al-Shehbaz et al., 1998).

Xu (1990). This analysis considered distribution, altitude, and habit, but also morphological characters describing hairs, inflorescences, flower details, silicles, seeds, and cotyledons. They concluded that minute pustules on the testa surface of the valves were a good character to separate Yinshania from Hilliella. Comparison of our molecular phylogenies with this cluster analysis based on 32 morphological and 3 ecological characters demonstrated the lack of congruency between morphological and molecular evolution. This cluster analysis separated Yinshania sensu Ma and Zhao (1979) from Hilliella sensu Zhang and Li (Zhang, 1986) (a similar resolution to the ITS data). Taxa such as H. paradoxa, H. lichuanensis, and H. changhuanensis are closely related to each other (as confirmed by molecular data by acc. nos. 11, 13, and 15 herein). However, this morphological cluster analysis also grouped H. guangdongensis (acc. no. 12 herein)

MORPHOLOGICAL CLUSTER ANALYSIS

A cluster analysis of morphological and ecological characters has been performed by Zhang and

into this group (Y. lichuanensis clade, Fig. 2). For both ITS and trnL intron sequence, H. guangdongensis is very divergent from others grouping with the Y. lichuanensis clade (Fig. 2). Hilliella alatipes var. micrantha and H. sinuata are separated with both molecular markers (Fig. 2), but are combined as a well-supported group in morphological cluster analysis (Zhang & Xu, 1990). In summary, within Hilliella there is little morphological agreement with our molecular data: (1) H. paradoxa, H. changhuaensis, and H. lichuanensis are closely related to each other (as Y. lichuanensis clade, Fig. 2); (2) H. hunanensis and H. rupicola grouped together on the ITS tree (but not based on trnL data, Fig. 2). No further correlation could be observed. None of the three data sets (ITS, trnL intron, morphology) is powerful enough to elucidate phylogenetic signal for the whole species complex. However, significant correlations could be observed when cpDNA- and nrDNA-derived phylogenies were compared, dividing the Hilliella/Cochleariella clade into several subgroups (Fig. 2) clearly separating Yinshania relatives from Hilliella/Cochleariella with the sole exception of Y. qianningensis.

ITS type that represents a mixture of the two original ITS sequences (in Gossypium, Wendel et al., 1995b; in Microseris, van Houten et al., 1993; in Microthlaspi, Mummenhoff et al., 1997). The third type of concerted evolution might have happened in H. sinuata (acc. no. 3). This accession showed a plastome type more similar to H. shuangpaiensis (acc. no. 4). However, ITS sequence types from putative parental ITS sequence types from H. sinuata (acc. no. 9) and H. shuangpaiensis (acc. no. 4) exhibit some additive features found in H. sinuata (acc. no. 3). Comparing these three sequences, there are 39 variable nucleotide positions (21 in ITS1 region, and 18 in ITS2 region). Within the ITS1 region, 17 out of 21 variable nucleotide positions (81%) are identical among the two H. sinuata accessions (nos. 3, 9); H. shuangpaiensis shared only three mutations with H. sinuata (acc. no. 9) and one mutation with H. sinuata (acc. no. 3). Within the ITS2 region both H. sinuata accessions have only one nucleotide position out of 18 variable nucleotide sites invariant, but H. shuangpaiensis (acc. no. 4) shared 15 positions (83%) with H. sinuata (acc. no. 3) and two positions with H. sinuata (acc. no. 9). These findings indicate that ITS type of H. sinuata (acc. no. 3) consists of a mixture of ITS types from relatives of H. shuangpaiensis (mostly ITS2 region) and H. sinuata (ITS1 region). The overall sequence divergence between H. shuangpaiensis (acc. no. 4) and H. sinuata (acc. no. 9) is 7.8%. Concerted evolution of ITS DNA loci has been shown several times to occur in the Brassicaceae (O'Kane et al., 1996; Mummenhoff et al., 1997; Koch et al., 1998b; Franzke et al., 1998) and other families (Wendel et al., 1995a, b; Buckler et al., 1997). Sequence divergence values of ITS types from putative parents, giving rise to hybrids in which concerted evolution has been observed, ranged from 3.1% (Microthlaspi natolicum vs. M. perfoliatum, Mummenhoff et al., 1997), 5.0% (Cardamine amara vs. C. rivularis auct., Franzke et al., 1998), to 6% (Arabidopsis thaliana vs. A. arenosa, O'Kane et al., 1996) comparable to a value of 7.8% found among H. shuangpaiensis versus H. sinuata. We conducted a split decomposition analysis to visualize conflicting phylogenetic signal indicating concerted evolution in groups among the Hilliella/ Cochleariella clade (Fig. 6). This analysis clearly indicates hybridization with subsequent concerted evolution of ITS regions in H. sinuata (acc. no. 3). Concerted evolution of ITS sequences greatly influences any interpretation of the ITS phylogeny. Since diploid members of the Brassicaceae such as Arabidopsis thaliana typically show 2 NOR loci,

#### HYBRIDIZATION, INTROGRESSION, CHLOROPLAST CAPTURE, AND CONCERTED EVOLUTION

The phylogeny based on plastid trnL intron sequence data reflects the maternal lineages because plastids are inherited maternally in most angiosperms, including the Brassicaceae (Harris & Ingram, 1991; Reboud & Zeyl, 1994). Introgression of a chloroplast type characteristic for the Hilliella/ Cochleariella clade into Yinshania gianningensis demonstrates possible gene flow between both groups. Because of the highly polyploid genomes of H. yixianensis, H. paradoxa, H. changhuaensis, and H. shuangpaiensis (represented by acc. nos. 2, 15, 11, and 4, respectively, in Fig. 2) with multiple rDNA loci, and the assumed hybridization within the Hilliella/Cochleariella clade and even with the Yinshania clade, there is a high probability of concerted ITS sequence evolution. In principle, there are three different ways that two different ITS copies evolve within a single individual: (1) unidirectional concerted evolution leads to the loss of one copy and fixation of the second (detected in H. rupicola acc. no. 14, herein; and in Gossypium, Wendel et al., 1995a); (2) both ITS copies are still present, which might be mostly the case in young hybridogenous taxa (detected in H. fumarioides acc. no. 17, and C. zhejiangensis acc. no. 21, Fig. 2; in Krigia, Kim & Jansen, 1994; in Arabidopsis, O'Kane et al., 1996); and (3) concerted evolution leads to a new

## Koch & Al-Shehbaz Chinese Yinshania

271

one could assume that in hexaploid *Hilliella/Cochleariella* taxa at least 6 major NOR loci are present. Therefore, sequencing of two individual ITS clones is not a sufficient survey to find all putative ITS types from a single individual. This undersampling leads to an underestimation of ITS type variation as well as the degree of hybridization and concerted evolution.

We found evidence suggesting concerted evolution and described three examples (H. fumarioides acc. no. 17, H. rupicola acc. no. 14, H. sinuata acc. no. 3) of possible hybridization and subsequent concerted evolution of ITS sequence. The overall amount of sequence divergence between taxa in this study demonstrates a relatively high age for the different lineages. In fact, sequence divergence values are much higher when compared to those obtained in infrageneric studies of closely related species of other Brassicaceae (e.g., Cochlearia s. str. < 1.75%, Koch et al. (1999a); Noccaea < 4.5%, Mummenhoff et al. (1997); Cardamine < 4.5%, Franzke et al. (1998)). Within the Yinshania clade, sequence distance values range up to 6%, but within the Hilliella/Cochleariella clade they range even higher, up to 27%.
